(54) Title: HUMAN METABOTROPIC GLUTAMATE RECEPTOR SUBTYPE mGluR6

(57) Abstract

In accordance with the present invention, there are provided nucleic acids encoding human metabotropic glutamate receptor subtype mGluR6, and the proteins encoded thereby. In addition to being useful for the production of metabotropic glutamate receptor subtype mGluR6, nucleic acids of the invention are also useful as probes, thus enabling those skilled in the art, without undue experimentation, to identify and isolate related human receptor subunits. In addition to disclosing a novel metabotropic glutamate receptor subtype, mGluR6, the present invention also comprises methods for using the invention receptor subtype to identify and characterize compounds which affect the function of such receptor subtype, e.g., agonists, antagonists, and modulators of glutamate receptor function.

HUMAN METABOTROPIC GLUTAMATE RECEPTOR SUBTYPE mGluR6

The present invention relates to nucleic acids and receptor proteins encoded thereby. Invention nucleic acids encode novel human metabotropic glutamate receptor subtypes. The invention also relates to methods for making
5 such receptor subtypes and for using the receptor proteins in assays designed to identify and characterize compounds which affect the function of such receptors, e.g., agonists, antagonists, and allosteric modulators of human metabotropic glutamate receptors.

10

BACKGROUND OF THE INVENTION

The amino acid L-glutamate is a major excitatory neurotransmitter in the mammalian central nervous system. Anatomical, biochemical and electrophysiological analyses suggest that glutamatergic systems are involved in a broad
15 array of neuronal processes, including fast excitatory synaptic transmission, regulation of neurotransmitter releases, long-term potentiation, learning and memory, developmental synaptic plasticity, hypoxic-ischemic damage and neuronal cell death, epileptiform seizures, as well as
20 the pathogenesis of several neurodegenerative disorders. See generally, Monaghan et al., Ann. Rev. Pharmacol. Toxicol. 29:365-402 (1980). This extensive repertoire of functions, especially those related to learning, neurotoxicity and neuropathology, has stimulated recent
25 attempts to describe and define the mechanisms through which glutamate exerts its effects.

Currently, glutamate receptor classification schemes are based on pharmacological criteria. Glutamate has been observed to mediate its effects through receptors
30 that have been categorized into two main groups: ionotropic and metabotropic. Ionotropic glutamate receptors contain integral cation-specific, ligand-gated

ion channels, whereas metabotropic glutamate receptors are G-protein-coupled receptors that transduce extracellular signals via activation of intracellular second messenger systems. Ionotropic receptors are further divided into at least two categories based on the pharmacological and functional properties of the receptors. The two main types of ionotropic receptors are NMDA (N-methyl-D-aspartate) receptors and kainate/AMPA (α -amino-3-hydroxy-5-methyl-4-isoxazole propionate, formerly called the quisqualic acid or QUIS receptor), receptors. While the metabotropic receptors bind to some of the same ligands that bind to ionotropic glutamate receptors, the metabotropic receptors alter synaptic physiology via GTP-binding proteins and second messengers such as adenylate cyclase, cyclic AMP, phosphodiesterases, cyclic GMP, diacylglycerol, inositol 1,4,5-triphosphate protein kinases and calcium [see, for example, Gundersen et al., Proc. R. Soc. London Ser. 221:127 (1984); Sladeczek et al., Nature 317:717 (1985); Nicoletti et al., J. Neurosci. 6:1905 (1986); Sugiyama et al., Nature 325:531 (1987); and Pin. J.-P. and Duvoisin, R. Neuropharmacology 34:1-26 (1994)].

The electrophysiological and pharmacological properties of metabotropic glutamate receptors have been studied using animal tissues and cell lines as a source of receptors, as well as non-human recombinant receptors. These studies have indicated that multiple subtypes of metabotropic glutamate receptors exist. Because of the potential physiological and pathological significance of metabotropic glutamate receptors, it is imperative (particularly for drug screening assays) to have available human sequences (i.e., DNA, RNA, proteins) which encode representative members of each of the various metabotropic glutamate receptor subtypes. The availability of such human sequences is critical to the development of human therapeutics that specifically target individual metabotropic receptor subtypes and will also enable the

investigation of receptor distribution in humans, the correlation of specific receptor modification with the occurrence of various disease states, etc.

BRIEF DESCRIPTION OF THE INVENTION

5 The present invention discloses novel nucleic acids encoding human metabotropic glutamate receptor protein subtype mGluR6, and the proteins encoded thereby. In addition to being useful for the production of metabotropic glutamate receptor subtype mGluR6 proteins,
10 these nucleic acids are also useful as probes, thus enabling those skilled in the art, without undue experimentation, to identify and isolate nucleic acids encoding related receptor subtypes.

 In addition to disclosing novel metabotropic
15 glutamate receptor protein subtypes, the present invention also comprises methods for using such receptor subtypes to identify and characterize compounds which affect the function of such receptors, e.g., agonists, antagonists, and modulators of glutamate receptor function. The
20 invention also comprises methods for determining whether unknown protein(s) are functional as metabotropic glutamate receptor subtypes.

BRIEF DESCRIPTION OF THE FIGURES

 Figure 1 presents a partial restriction map of a
25 CMV promoter-based mammalian vector containing the mGluR6-encoding DNA and designated pCMV-T7-2(-SD/SA)-hmGluR6.

DETAILED DESCRIPTION OF THE INVENTION

 In accordance with the present invention, there are provided isolated nucleic acids encoding human
30 metabotropic glutamate receptor subtype mGluR6. Also

provided are protein(s) encoded by the above-described nucleic acids, as well as antibodies generated against the protein(s). In other aspects of the present invention, there are provided nucleic acid probes comprising
5 metabotropic glutamate receptor subtype-selective portions of the above-described nucleic acids. In a still further aspect, cells containing such nucleic acids and eucaryotic cells expressing such nucleic acids are provided.

As employed herein, the phrase "human
10 metabotropic glutamate receptor subtypes" refers to isolated and/or purified proteins which participate in the G-protein-coupled response of cells to glutamatergic ligands. Such receptor subtypes are individually encoded by distinct genes which do not encode other metabotropic
15 glutamate receptor subtypes (i.e., each subtype is encoded by a unique gene). Complementary DNA clones encoding various human metabotropic glutamate receptor subtypes (e.g., mGluR1, mGluR2, mGluR3, mGluR5) have been isolated. See, for example, WO 94/29449, which is hereby incorporated
20 by reference herein in its entirety. Such receptor subtypes are typically characterized by having seven putative transmembrane domains, preceded by a large putative extracellular amino-terminal domain and followed by a large putative intracellular carboxy-terminal domain.
25 Metabotropic glutamate receptors share essentially no amino acid sequence homology with other G-protein-coupled receptors that are not metabotropic glutamate receptors.

Regarding the inter-relationship between each of the metabotropic glutamate receptor subtypes, the amino
30 acid sequences of mGluR1 receptor subtypes are generally less than about 70% identical to the amino acid sequences of other human metabotropic glutamate receptor subtypes, with identities less than about 45% typically observed. The amino acid sequences of mGluR2 receptor subtypes are
35 generally less than 60% identical to the amino acid

sequences of other human metabotropic glutamate receptor subtypes, with identities of less than 45% typically observed. The amino acid sequences of mGluR3 receptor subtypes are generally less than 60% identical to the amino acid sequences of other human metabotropic glutamate receptor subtypes, with identities of less than 45% typically observed. The amino acid sequences of mGluR5 receptor subtypes are generally less than 70% identical to the amino acid sequences of other human metabotropic glutamate receptor subtypes, with identities of less than 45% typically observed. The amino acid sequences of mGluR6 receptor subtypes are generally less than 70% identical to the amino acid sequences of other human metabotropic glutamate receptor subtypes, with identities of less than 40% typically observed.

Also included within the above definition are variants thereof encoded by mRNA generated by alternative splicing of a primary transcript, as well as fragments thereof which retain one or more of the above physiological and/or physical properties.

Use of the terms "isolated" or "purified" in the present specification and claims as a modifier of DNA, RNA, polypeptides or proteins means that the DNA, RNA, polypeptides or proteins so designated have been produced in such form by the hand of man, and thus are separated from their native in vivo cellular environment. As a result of this human intervention, the recombinant DNAs, RNAs, polypeptides and proteins of the invention are useful in ways that the DNAs, RNAs, polypeptides or proteins as they naturally occur are not, such as identification of selective drugs or compounds.

The term "functional", when used herein as a modifier of receptor protein(s) of the present invention, means that binding of glutamatergic ligands (such as ACPD

or ACPD-like ligands, glutamate, L-AP4, L-SOP, and the like) to said receptor protein(s) modifies the receptor interaction with G-proteins, which in turn affects the levels of intracellular second messengers, leading to a variety of physiological effects. Stated another way, "functional" means that a response is generated as a consequence of agonist activation of receptor protein(s).

As used herein, a splice variant refers to variant metabotropic glutamate receptor subtype-encoding nucleic acid(s) produced by differential processing of primary transcript(s) of genomic DNA, resulting in the production of more than one type of mRNA. cDNA derived from differentially processed primary transcript will encode metabotropic glutamate receptor subtypes that have regions of complete amino acid identity and regions having different amino acid sequences. Thus, the same genomic sequence can lead to the production of multiple, related mRNAs and proteins. Both the resulting mRNAs and proteins are referred to herein as "splice variants".

Accordingly, also contemplated within the scope of the present invention are nucleic acids that encode metabotropic glutamate receptor subtypes as defined above, but that by virtue of degeneracy of the genetic code do not necessarily hybridize to the disclosed nucleic acids under specified hybridization conditions. Such subtypes also form functional receptors, as assessed by methods described herein or known to those of skill in the art. Typically, unless a metabotropic glutamate receptor subtype is encoded by RNA that arises from alternative splicing (i.e., a splice variant), metabotropic glutamate receptor subtype-encoding nucleic acids and the metabotropic glutamate receptor protein encoded thereby share substantial sequence homology with at least one of the metabotropic glutamate receptor subtype nucleic acids (and proteins encoded thereby) described herein. It is understood that DNA or

RNA encoding a splice variant may share less than 90% overall sequence homology with the DNA or RNA provided herein, but include regions of nearly 100% homology to a DNA fragment described herein, and encode an open reading
5 frame that includes start and stop codons and encodes a functional metabotropic glutamate receptor subtype.

Exemplary DNA sequences encoding human mGluR6 subtypes are represented by nucleotides which encode substantially the same amino acid sequence as set forth in
10 SEQ ID NO:2, or amino acid sequences that have substantial sequence homology with the amino acid sequence set forth in SEQ ID NO:2. Presently preferred sequences encode the amino acid sequence set forth in SEQ ID NO:2.

An exemplary splice variant of the above-
15 described DNA sequences encodes at least the 22 amino acid residues set forth in SEQ ID NO:4, which at least in part define an alternate 5' portion of mGluR6. Presently preferred splice variants comprise at least the 67 nucleotides set forth in SEQ ID NO:3. Thus, one potential
20 splice variant of mGluR6-encoding DNA comprises nucleotides 896-2961 of SEQ ID NO:1, preceded by nucleotides 1-67 of SEQ ID NO:3.

Exemplary DNA can alternatively be characterized as those nucleotide sequences which encode an human mGluR6
25 subtype and hybridize under high-stringency conditions to substantially the entire sequence of SEQ ID NO:1, or substantial portions thereof (i.e., typically at least 46 or more contiguous nucleotides thereof).

Stringency of hybridization is used herein to
30 refer to conditions under which polynucleic acid hybrids are stable. As known to those of skill in the art, the stability of hybrids is reflected in the melting

temperature (T_m) of the hybrids. T_m can be approximated by the formula:

$$81.5^{\circ}\text{C} - 16.6(\log_{10}[\text{Na}^+]) + 0.41(\%G+C) - 600/l,$$

where l is the length of the hybrids in nucleotides. T_m decreases approximately 1-1.5°C with every 1% decrease in sequence homology. In general, the stability of a hybrid is a function of sodium ion concentration and temperature. Typically, the hybridization reaction is performed under conditions of lower stringency, followed by washes of varying, but higher, stringency. Reference to hybridization stringency relates to such washing conditions. Thus, as used herein:

(1) HIGH STRINGENCY conditions, with respect to fragment hybridization, refer to conditions that permit hybridization of only those nucleic acid sequences that form stable hybrids in 0.018M NaCl at 65°C (i.e., if a hybrid is not stable in 0.018M NaCl at 65°C, it will not be stable under high stringency conditions, as contemplated herein). High stringency conditions can be provided, for example, by hybridization in 50% formamide, 5X Denhart's solution, 5X SSPE, 0.2% SDS at 42°C, followed by washing in 0.1X SSPE, and 0.1% SDS at 65°C;

(2) MODERATE STRINGENCY conditions, with respect to fragment hybridization, refer to conditions equivalent to hybridization in 50% formamide, 5X Denhart's solution, 5X SSPE, 0.2% SDS at 42°C, followed by washing in 0.2X SSPE, 0.2% SDS, at 65°C; and

- 5 (3) LOW STRINGENCY conditions, with respect to fragment hybridization, refer to conditions equivalent to hybridization in 10% formamide, 5X Denhart's solution, 6X SSPE, 0.2% SDS at 42°C, followed by washing in 1X SSPE, 0.2% SDS, at 50°C.
- 10 (4) HIGH STRINGENCY conditions, with respect to oligonucleotide (i.e., synthetic DNA \leq about 30 nucleotides in length) hybridization, refer to conditions equivalent to hybridization in 10% formamide, 5X Denhart's solution, 6X SSPE, 0.2% SDS at 42°C, followed by washing in 1X SSPE, and 0.2% SDS at 50°C.

15 It is understood that these conditions may be duplicated using a variety of buffers and temperatures and that they are not necessarily precise.

Denhart's solution and SSPE (see, e.g., Sambrook, Fritsch, and Maniatis, in: Molecular Cloning, A Laboratory
20 Manual, Cold Spring Harbor Laboratory Press, 1989) are well known to those of skill in the art as are other suitable hybridization buffers. For example, SSPE is pH 7.4 phosphate-buffered 0.18M NaCl. SSPE can be prepared, for example, as a 20X stock solution by dissolving 175.3 g of
25 NaCl, 27.6 g of NaH_2PO_4 and 7.4 g EDTA in 800 ml of water, adjusting the pH to 7.4, and then adding water to 1 liter. Denhart's solution (see, Denhart (1966) Biochem. Biophys. Res. Commun. 23:641) can be prepared, for example, as a 50X
30 stock solution by mixing 5 g Ficoll (Type 400, Pharmacia LKB Biotechnology, INC., Piscataway, NJ), 5 g of polyvinylpyrrolidone, 5 g bovine serum albumin (Fraction V; Sigma, St. Louis, MO) water to 500 ml and filtering to remove particulate matter.

Especially preferred sequences encoding human mGluR6 subtypes are those which have substantially the same nucleotide sequence as the coding sequences in SEQ ID NO:1; with polynucleic acid having the same sequence as the
5 coding sequence in SEQ ID NO:1 being most preferred.

As used herein, the phrase "substantial sequence homology" refers to nucleotide sequences which share at least about 90% identity, and amino acid sequences which typically share more than 95% amino acid identity. It is
10 recognized, however, that proteins (and DNA or mRNA encoding such proteins) containing less than the above-described level of homology arising as splice variants or that are modified by conservative amino acid substitutions (or substitution of degenerate codons) are contemplated to
15 be within the scope of the present invention.

The phrase "substantially the same" is used herein in reference to the nucleotide sequence of DNA, the ribonucleotide sequence of RNA, or the amino acid sequence of protein, that have slight and non-consequential sequence
20 variations from the actual sequences disclosed herein. Species that are substantially the same are considered to be equivalent to the disclosed sequences and as such are within the scope of the appended claims. In this regard, "slight and non-consequential sequence variations" mean
25 that sequences that are substantially the same as the DNA, RNA, or proteins disclosed and claimed herein are functionally equivalent to the human-derived sequences disclosed and claimed herein. Functionally equivalent sequences will function in substantially the same manner to
30 produce substantially the same compositions as the human-derived nucleic acid and amino acid compositions disclosed and claimed herein. In particular, functionally equivalent DNAs encode human-derived proteins that are the same as those disclosed herein or that have conservativ amino acid
35 variations, such as substitution of a non-polar residue for

another non-polar residue or a charged residue for a similarly charged residue. These changes include those recognized by those of skill in the art as those that do not substantially alter the tertiary structure of the protein.

DNA encoding human metabotropic glutamate receptor subtypes may be isolated by screening suitable human cDNA or human genomic libraries under suitable hybridization conditions with DNA disclosed herein (e.g., nucleotides derived from SEQ ID NOS:1 or 3). Suitable libraries can be prepared from neural tissue samples, e.g., retina tissue, cell lines, and the like. For example, the library can be screened with a portion of DNA including substantially the entire receptor subtype-encoding sequence thereof, or the library may be screened with a suitable oligonucleotide probe based on a portion of the DNA.

As used herein, a probe is single-stranded DNA or RNA that has a sequence of nucleotides that includes at least about 46 contiguous bases that are the same as (or the complement of) any 46 or more contiguous bases set forth in SEQ ID NOS:1 or 3. Preferred regions from which to construct probes include 5' and/or 3' coding sequences, sequences predicted to encode transmembrane domains, sequences predicted to encode cytoplasmic loops, ligand binding sites, and the like.

Either the full-length cDNA clones, fragments thereof, or oligonucleotides based on portions of the cDNA clones can be used as probes, preferably labeled with suitable label means for ready detection. When fragments are used as probes, DNA sequences for such probes will preferably be derived from the carboxyl end-encoding portion of the DNA, and most preferably will include predicted transmembrane domain-encoding portions of the DNA sequence (the domains can be predicted based on hydropathy

analysis of the deduced amino acid sequence using, for example, the method of Kyte and Doolittle (1982), J. Mol. Biol. Vol. 157:105). These probes can be used, for example, for the identification and isolation of additional
5 members of the glutamate receptor family.

As a particular application of the invention sequences, genetic screening can be carried out using the nucleotide sequences of the invention as probes. Thus, nucleic acid samples from patients having neuropathological
10 conditions suspected of involving alteration/modification of any one or more of the glutamate receptors can be screened with appropriate probes to determine if any abnormalities exist with respect to any of the endogenous glutamate receptors. Similarly, patients having a family
15 history of disease states related to glutamate receptor dysfunction can be screened to determine if they are also predisposed to such disease states.

In accordance with another embodiment of the present invention, there is provided a method for
20 identifying DNA encoding human metabotropic glutamate receptor protein subtypes, said method comprising:

contacting human DNA with a nucleic acid probe as described above, wherein said contacting is carried out under low- to moderate-stringency hybridization conditions
25 when the probe used is a polynucleic acid fragment, or under high-stringency hybridization conditions when the probe used is an oligonucleotide, and

identifying DNA(s) which hybridize to said probe.

After screening the library, positive clones are
30 identified by detecting a hybridization signal; the identified clones are characterized by restriction enzyme mapping and/or DNA sequence analysis, and then examined by comparison with the sequences set forth herein to ascertain whether they include DNA encoding a complete metabotropic

glutamate receptor subtype (i.e., if they include translation initiation and termination codons). If the selected clones are incomplete, they may be used to rescreen the same or a different library to obtain overlapping clones. If the library is genomic, then the overlapping clones may include exons and introns. If the library is a cDNA library, then the overlapping clones will include an open reading frame. In both instances, complete clones may be identified by comparison with the DNA and deduced amino acid sequences provided herein.

The mGluR6-encoding DNA clones provided herein may be used to isolate genomic clones encoding the mGluR6 subtype and to isolate any splice variants by screening libraries prepared from different neural tissues. Nucleic acid amplification techniques, which are well known in the art, can be used to locate DNA encoding splice variants of human metabotropic glutamate receptor subtypes. This is accomplished by employing oligonucleotides based on DNA sequences surrounding predicted intron/exon boundaries as primers for amplifying human RNA or genomic DNA. Size and sequence determinations of the amplification products can reveal the existence of splice variants. Furthermore, isolation of human genomic DNA sequences by hybridization can yield DNA containing multiple exons, separated by introns, that may correspond to different splice variants of transcripts encoding human metabotropic glutamate receptor subtypes.

It has been found that not all metabotropic glutamate receptor subtypes (and variants thereof) are expressed in all neural tissues or in all portions of the brain. Thus, in order to isolate cDNA encoding a particular subtype (or splice variants thereof), it is preferable to screen libraries prepared from different neuronal or neural tissues or cells. Preferred libraries for obtaining DNA encoding each subtype include:

cerebellum to isolate human mGluR1-encoding DNAs;
hippocampus to isolate human mGluR2-encoding DNAs;
hippocampus and cerebellum to isolate mGluR3-encoding DNAs;
hippocampus and cerebellum to isolate mGluR5-encoding DNAs;
5 retina to isolate mGluR6-encoding DNAs; and the like.

Once DNA encoding a particular receptor subtype has been isolated, ribonuclease (RNase) protection assays can be employed to determine which tissues express mRNA encoding such subtype (or splice variant thereof). These
10 assays provide a sensitive means for detecting and quantitating an RNA species in a complex mixture of total cellular RNA. The subtype DNA is labeled and hybridized with cellular RNA. If complementary mRNA is present in the cellular RNA, a DNA-RNA hybrid results. The RNA sample is
15 then treated with RNase, which degrades single-stranded RNA. Any RNA-DNA hybrids are protected from RNase degradation and can be visualized by gel electrophoresis and autoradiography. *In situ* hybridization techniques can also be used to determine which tissues express mRNAs
20 encoding particular metabotropic glutamate receptor subtypes. Thus, labeled subtype DNAs can be hybridized to different brain region slices to visualize subtype mRNA expression.

The distribution of expression of some human
25 metabotropic glutamate receptor subtypes may differ from the distribution of such receptors in rat. For example, even though RNA encoding the rat mGluR5 subtype is abundant in rat hippocampus, but is not abundant in rat cerebellum [see, e.g., Abe et al., J. Biol. Chem. 267: 13361-13368
30 (1992)], human mGluR5-encoding cDNAs were successfully obtained from human cerebellum cDNA libraries.

The above-described nucleotide sequences can be incorporated into vectors for further manipulation. As used herein, vector (or plasmid) refers to discrete

elements that are used to introduce heterologous DNA into cells for either expression or replication thereof. Selection and use of such vehicles are well within the skill of the artisan.

5 An expression vector includes vectors capable of expressing DNAs that are operatively linked with regulatory sequences, such as promoter regions, that are capable of regulating expression of such DNA fragments. Thus, an expression vector refers to a recombinant DNA or RNA
10 construct, such as a plasmid, a phage, recombinant virus or other vector that, upon introduction into an appropriate host cell, results in expression of the cloned DNA. Appropriate expression vectors are well known to those of skill in the art and include those that are replicable in
15 eukaryotic cells and/or prokaryotic cells and those that remain episomal or those which integrate into the host cell genome. Presently preferred plasmids for expression of invention metabotropic glutamate receptor subtypes in eukaryotic host cells, particularly mammalian cells,
20 include cytomegalovirus (CMV) promoter-containing vectors such as pCMV-T7-2(-SD/SA) and pCMV-T7-3(-SD/SA), pCDNA3, and the like, as well as SV40 promoter-containing vectors and MMTV LTR promoter-containing vectors, such as pMMTVT7(+) or pMMTVT7(-) (modified versions of pMAMneo
25 (Clontech, Palo Alto, CA), prepared as described herein), and the like.

As used herein, a promoter region refers to a segment of DNA that controls transcription of DNA to which it is operatively linked. The promoter region includes
30 specific sequences that are sufficient for RNA polymerase recognition, binding and transcription initiation. This portion of the promoter region is referred to as the promoter. In addition, the promoter region includes sequences that modulate this recognition, binding and
35 transcription initiation activity of RNA polymerase. These

sequences may be *cis* acting or may be responsive to *trans* acting factors. Promoters, depending upon the nature of the regulation, may be constitutive or regulated. Exemplary promoters contemplated for use in the practice of the present invention include the SV40 early promoter, the cytomegalovirus (CMV) promoter, the mouse mammary tumor virus (MMTV) steroid-inducible promoter, Moloney murine leukemia virus (MMLV) promoter, and the like.

As used herein, the term "operatively linked" refers to the functional relationship of DNA with regulatory and effector sequences of nucleotides, such as promoters, enhancers, transcriptional and translational stop sites, and other signal sequences. For example, operative linkage of DNA to a promoter refers to the physical and functional relationship between the DNA and the promoter such that the transcription of such DNA is initiated from the promoter by an RNA polymerase that specifically recognizes, binds to and transcribes the DNA. In order to optimize expression and/or *in vitro* transcription, it may be necessary to remove, add or alter 5' and/or 3' untranslated portions of the clones to eliminate extra, potentially inappropriate alternative translation initiation (*i.e.*, start) codons or other sequences that may interfere with or reduce expression, either at the level of transcription or translation. Alternatively, consensus ribosome binding sites (see, for example, Kozak (1991) *J. Biol. Chem.* 266:19867-19870) can be inserted immediately 5' of the start codon and may enhance expression. Likewise, alternative codons, encoding the same amino acid, can be substituted for coding sequences of the metabotropic glutamate receptor subunits in order to enhance transcription (*e.g.*, the codon preference of the host cells can be adopted, the presence of G-C rich domains can be reduced, and the like). Furthermore, for potentially enhanced expression of metabotropic glutamate receptor subunits in amphibian

oocytes, the subunit coding sequence can optionally be incorporated into an expression construct wherein the 5'- and 3'-ends of the coding sequence are contiguous with *Xenopus* β -globin gene 5' and 3' untranslated sequences, respectively. For example, metabotropic glutamate receptor subunit coding sequences can be incorporated into vector pSP64T (see Krieg and Melton (1984) in *Nucleic Acids Research* 12:7057-7070), a modified form of pSP64 (available from Promega, Madison, WI). The coding sequence is inserted between the 5' end of the β -globin gene and the 3' untranslated sequences located downstream of the SP6 promoter. In vitro transcripts can then be generated from the resulting vector. The desirability of (or need for) such modifications may be empirically determined.

As used herein, expression refers to the process by which polynucleic acids are transcribed into mRNA and translated into peptides, polypeptides, or proteins. If the polynucleic acid is derived from genomic DNA, expression may, if an appropriate eukaryotic host cell or organism is selected, include splicing of the mRNA.

Particularly preferred base vectors which contain regulatory elements that can be linked to human metabotropic receptor-encoding DNAs for transfection of mammalian cells are cytomegalovirus (CMV) promoter-based vectors such as pCMV-T7-2(-SD/SA) and pCMV-T7-3(-SD/SA) (described herein) or pcDNA3 (Invitrogen, San Diego, CA), MMTV promoter-based vectors such as pMMTVT7(+) or pMMTVT7(-) (as described herein), and SV40 promoter-based vectors such as pSV β (Clontech, Palo Alto, CA).

Full-length DNAs encoding human metabotropic glutamate receptor subtypes can be inserted into vectors pMMTVT7(+), pMMTVT7(-), pCMV-T7-2(-SD/SA) or pCMV-T7-3(-SD/SA). pCMV-T7-2(-SD/SA) (and pCMV-T7-3(-SD/SA)) are pUC19-based mammalian cell

expression vectors containing the CMV promoter/enhancer, a T7 bacteriophage RNA polymerase promoter positioned downstream of the promoter, followed by an SV40 polyadenylation signal and a polylinker between the T7 promoter and the polyadenylation signal. Placement of metabotropic glutamate receptor subtype DNA between the CMV promoter and SV40 polyadenylation signal should provide for constitutive expression of the foreign DNA in a mammalian host cell transfected with the construct.

10 Vectors pMMTVT7(+) and pMMTVT7(-) were prepared by modifying vector pMAMneo (Clontech, Palo Alto, CA). pMAMneo is a mammalian expression vector that contains the Rous Sarcoma Virus (RSV) long terminal repeat (LTR) enhancer, linked to the dexamethasone-inducible mouse
15 mammary tumor virus (MMTV)-LTR promoter, followed by SV40 splicing and polyadenylation sites. pMAMneo also contains the *E. coli* neo gene for selection of transformants, as well as the β -lactamase gene (encoding a protein which imparts ampicillin-resistance) for propagation in *E. coli*.

20 Vector pMMTVT7(+) can be generated by modification of pMAMneo to remove the neo gene and insert the multiple cloning site and T7 and T3 promoters from pBluescript (Stratagene, La Jolla, CA). Thus, pMMTVT7(+) contains the RSV-LTR enhancer linked to the MMTV-LTR
25 promoter, a T7 bacteriophage RNA polymerase promoter positioned downstream of the MMTV-LTR promoter, a polylinker positioned downstream of the T7 promoter, a T3 bacteriophage RNA polymerase promoter positioned downstream of the T7 promoter, and SV40 splicing and polyadenylation
30 sites positioned downstream of the T3 promoter. The β -lactamase gene (encoding a protein which imparts ampicillin-resistance) from pMAMneo is retained in pMMTVT7(+), although it is incorporated in the reverse orientation relative to the orientation in pMAMneo.

Vector pMMTVT7(-) is identical to pMMTVT7(+) except that the positions of the T7 and T3 promoters are switched, i.e., the T3 promoter in pMMTVT7(-) is located where the T7 promoter is located in pMMTVT7(+), and the T7 promoter in pMMTVT7(-) is located where the T3 promoter is located in pMMTVT7(+). Therefore, vectors pMMTVT7(+) and pMMTVT7(-) contain all of the regulatory elements required for expression of heterologous DNA in a mammalian host cell, wherein the heterologous DNA has been incorporated into the vectors at the polylinker. In addition, because the T7 and T3 promoters are located on either side of the polylinker, these plasmids can be used for synthesis of in vitro transcripts of heterologous DNA that has been subcloned into the vectors at the polylinker.

For inducible expression of human metabotropic glutamate receptor subtype-encoding DNA in a mammalian cell, the DNA can be inserted into a plasmid such as pMMTVT7(+) or pMMTVT7(-). These plasmids contain the mouse mammary tumor virus (MMTV) LTR promoter for steroid-inducible expression of operatively associated foreign DNA. If the host cell does not express endogenous glucocorticoid receptors required for uptake of glucocorticoids (i.e., inducers of the MMTV LTR promoter) into the cell, it is necessary to additionally transfect the cell with DNA encoding the glucocorticoid receptor (ATCC accession no. 67200). For synthesis of in vitro transcripts, the human mGluR cDNA can also be subcloned into pIBI24 (International Biotechnologies, Inc., New Haven, CT), pCMV-T7-2(-SD/SA) or pCMV-T7-3(-SD/SA), pMMTVT7(+), pMMTVT7(-), pBluescript (Stratagene, La Jolla, CA), pGEM72 (Promega, Madison, WI), or the like.

Incorporation of cloned DNA into a suitable expression vector, transfection of eukaryotic cells with a plasmid vector or a combination of plasmid vectors, each encoding one or more distinct genes or with linear DNA, and

selection of transfected cells are well known in the art (see, e.g., Sambrook et al. (1989) Molecular Cloning: A Laboratory Manual, Second Edition, Cold Spring Harbor Laboratory Press). Heterologous DNA may be introduced into
5 host cells by any method known to those of skill in the art, such as transfection with a vector encoding the heterologous DNA by CaPO_4 precipitation (see, e.g., Wigler et al. (1979) Proc. Natl. Acad. Sci. 76:1373-1376). Recombinant cells can then be cultured under conditions
10 whereby the subtype(s) encoded by the DNA is (are) expressed. Preferred cells include mammalian cells (e.g., HEK293, CHO, BHK, GH3 and Ltk cells), yeast cells (e.g., methylotrophic yeast cells, such as *Pichia pastoris*), bacterial cells (e.g., *Escherichia coli*), and the like.

15 While the DNA provided herein may be expressed in any eukaryotic cell, including yeast cells (such as, for example, *P. pastoris* (see U.S. Patent Nos. 4,882,279, 4,837,148, 4,929,555 and 4,855,231), *Saccharomyces cerevisiae*, *Candida tropicalis*, *Hansenula polymorpha*, and
20 the like), mammalian expression systems, including commercially available systems and other such systems known to those of skill in the art which express G-proteins (either endogenously or recombinantly), for expression of DNA encoding the human metabotropic glutamate receptor
25 subtypes provided herein are presently preferred. *Xenopus* oocytes are preferred for expression of in vitro mRNA transcripts of DNA encoding those human metabotropic receptor subtypes that are coupled to the PI hydrolysis/ Ca^{++} signalling pathways. An endogenous inositol triphosphate
30 second messenger-mediated pathway in oocytes permits functional expression of the subclass of inositol triphosphate pathway-linked human metabotropic receptors in these cells. Oocytes expressing recombinant human
metabotropic receptors respond to agonists via the oocyte
35 G-protein-coupled IP_3 generation pathway, which stimulates release of Ca^{++} from internal stores, and reportedly

activates a chloride channel that can be detected as a delayed oscillatory current by voltage-clamp recording.

Host cells for functional recombinant expression of human metabotropic receptors preferably express endogenous or recombinant guanine nucleotide-binding proteins (i.e., G-proteins). G-proteins are a highly conserved family of membrane-associated proteins composed of α , β and γ subunits. The α subunit, which binds GDP and GTP, differs in different G-proteins. The attached pair of β and γ subunits may or may not be unique; different α chains may be linked to an identical $\beta\gamma$ pair or to different pairs [Linder and Gilman, Sci. Am. 267:56-65 (1992)]. More than 30 different cDNAs encoding G protein α subunits have been cloned [Simon et al., Science 252:802 (1991)]. Four different β polypeptide sequences are known [Simon et al., Science 252:802 (1991)]. Three of five identified γ cDNAs have been cloned [Hurley et al., PNAS U.S.A. 81:6948 (1984); Gautam et al., Science 244:971 (1989); and Gautam et al., PNAS U.S.A. 87:7973 (1990)]. The sequences of a fourth γ cDNA [Kleuss et al., Science 259:832 (1993)] and a fifth γ cDNA [Fisher and Aronson, Mol. Cell. Bio. 12:1585 (1992)] have been established, and additional γ subtypes may exist [Tamir et al., Biochemistry 30:3929 (1991)]. G-proteins switch between active and inactive states by guanine nucleotide exchange and GTP hydrolysis. Inactive G protein is stimulated by a ligand-activated receptor to exchange GDP for GTP. In the active form, the α subunit, bound to GTP, dissociates from the $\beta\gamma$ complex, and the subunits then interact specifically with cellular effector molecules to evoke a cellular response. Because different G-proteins can interact with different effector systems (e.g., phospholipase C, adenylyl cyclase systems) and different receptors, it is useful to investigate different host cells for expression of different recombinant human metabotropic receptor subtypes. Alternatively, host cells can be transfected with G-protein

subunit-encoding DNAs for heterologous expression of differing G proteins.

In preferred embodiments, human metabotropic glutamate receptor subtype-encoding DNA is ligated into a vector, and introduced into suitable host cells to produce transformed cell lines that express a specific human metabotropic glutamate receptor subtype, or specific combinations of subtypes. The resulting cell lines can then be produced in quantity for reproducible quantitative analysis of the effects of known or potential drugs on receptor function. In other embodiments, mRNA may be produced by *in vitro* transcription of DNA encoding each subtype. This mRNA, either from a single subtype clone or from a combination of clones, can then be injected into *Xenopus* oocytes where the mRNA directs the synthesis of functional human metabotropic glutamate receptor subtypes. Alternatively, the subtype-encoding DNA can be directly injected into oocytes for expression of functional human metabotropic glutamate receptor subtypes. The transfected mammalian cells or injected oocytes may then be used in the methods of drug screening provided herein.

Eukaryotic cells in which DNA or RNA may be introduced include any cells that are transfectable by such DNA or RNA or into which such DNA or RNA may be injected and which cells express (endogenously or recombinantly) G-proteins. Preferred cells are those that express little, if any, endogenous metabotropic receptors and can be transiently or stably transfected and also express invention DNA and RNA. Presently most preferred cells are those that can form recombinant or heterologous human metabotropic glutamate receptors comprising one or more subtypes encoded by the heterologous DNA. Such cells may be identified empirically or selected from among those known to be readily transfected or injected.

Exemplary cells for introducing DNA include cells of mammalian origin (e.g., COS cells, mouse L cells, Chinese hamster ovary (CHO) cells, human embryonic kidney (HEK) cells, baby hamster kidney (BHK) cells, rat pituitary tumor (GH3) cells, African green monkey cells and other such cells known to those of skill in the art), amphibian cells (e.g., *Xenopus laevis* oocytes), yeast cells (e.g., *Saccharomyces cerevisiae*, *Pichia pastoris*), and the like. Exemplary cells for expressing injected RNA transcripts include *Xenopus laevis* oocytes. Cells that are preferred for transfection of DNA are known to those of skill in the art or may be empirically identified, and include HEK293 (which are available from ATCC under accession #CRL 1573); Ltk cells (which are available from ATCC under accession #CCL1.3); COS-7 cells (which are available from ATCC under accession #CRL 1651); CHO cells (which are available from ATCC under accession #CRL9618, CCL61 or CRL9096); DG44 cells (dhfr CHO cells; see, e.g., Urlaub et al. (1986) Cell. Molec. Genet. 12: 555); GH3 cells (available from the ATCC under accession #CCL82.1) and BHK cells (see Waechter and Baserga, PNAS U.S.A. 79:1106-1110 (1982); also available from ATCC under accession #CRL6281). Presently preferred cells include CHO cells and HEK293 cells, particularly HEK293 cells that can be frozen in liquid nitrogen and then thawed and regrown (for example, those described in U.S. Patent No. 5,024,939 to Gorman (see, also, Stillman et al. (1985) Mol. Cell. Biol. 5:2051-2060)), DG44, Ltk cells, and the like. Those of skill in the art recognize that comparison experiments should also be carried out with whatever host cells are employed to determine background levels of glutamate production induced by the ligand employed, as well as background levels of glutamate present in the host cell in the absence of ligand.

DNA may be stably incorporated into cells or may be transiently expressed using methods known in the art.

Stably transfected mammalian cells may be prepared by transfecting cells with an expression vector having a selectable marker gene (such as, for example, the gene for thymidine kinase, dihydrofolate reductase, neomycin resistance, and the like), and growing the transfected cells under conditions selective for cells expressing the marker gene. To prepare transient transfectants, mammalian cells are transfected with a reporter gene (such as the *E. coli* β -galactosidase gene) to monitor transfection efficiency. Selectable marker genes are typically not included in the transient transfections because the transfectants are typically not grown under selective conditions, and are usually analyzed within a few days after transfection.

15 To produce such stably or transiently transfected cells, the cells should be transfected with a sufficient concentration of subtype-encoding nucleic acids to form human metabotropic glutamate receptors indicative of the human subtypes encoded by the heterologous DNA. The precise amounts of DNA encoding the subtypes may be empirically determined and optimized for a particular subtype, cells and assay conditions. Recombinant cells that express metabotropic glutamate receptors containing subtypes encoded only by the heterologous DNA or RNA are especially preferred.

Heterologous DNA may be maintained in the cell as an episomal element or may be integrated into chromosomal DNA of the cell. The resulting recombinant cells may then be cultured or subcultured (or passaged, in the case of mammalian cells) from such a culture or a subculture thereof. Methods for transfection, injection and culturing recombinant cells are known to the skilled artisan. Similarly, the human metabotropic glutamate receptor subtypes may be purified using protein purification methods known to those of skill in the art. For example,

antibodies or other ligands that specifically bind to one or more subtypes may be used for affinity purification of a given metabotropic glutamate receptor subtype.

As used herein, heterologous or foreign DNA and RNA are used interchangeably and refer to DNA or RNA that does not occur naturally as part of the genome of the cell in which it is present or to DNA or RNA which is found in a location or locations in the genome that differ from that in which it occurs in nature. Typically, heterologous or foreign DNA and RNA refers to DNA or RNA that is not endogenous to the host cell and has been artificially introduced into the cell. Examples of heterologous DNA include DNA that encodes a human metabotropic glutamate receptor subtype, DNA that encodes RNA or proteins that mediate or alter expression of endogenous DNA by affecting transcription, translation, or other regulatable biochemical processes, and the like. The cell that expresses heterologous DNA may contain DNA encoding the same or different expression products. Heterologous DNA need not be expressed and may be integrated into the host cell genome or maintained episomally.

Those of skill in the art can readily identify a variety of assays which can be used to detect the expression of functional mGluRs. Examples include PI turnover assays [see, e.g., Nakajima et al., J. Biol. Chem. 267:2437-2442 (1992) and Example 3.C.2], adenylate cyclase assays, cAMP assays [see, e.g., Nakajima et al., supra and Example 3.C.4.], calcium ion flux assays [see, e.g., Ito et al., J. Neurochem. 56:531-540 (1991) and Example 3.C.1], cGMP assays [see, e.g., Steiner et al., J. Biol. Chem. 247:1106-1113 (1972)], cGMR-specific phosphodiesterase assays [see, e.g., Liebman et al., Meth. Enzymol. 81:532-542 (1982)], arachidonic acid release assays [see, e.g., Felder et al., J. Biol. Chem. 264:20356-20362 (1989)], and the like. Methods of analyzing changes in intracellular

Ca²⁺ and cyclic nucleotide concentrations are known to those of skill in the art. One such method involves co-transfection of mGluR-expressing cells with a Ca²⁺- and/or cyclic nucleotide-responsive gene promoter linked to DNA encoding a reporter molecule (e.g., luciferase, chloramphenicol acetyltransferase, and the like). Activation of the mGluRs expressed in such cells is detected as a change in reporter gene transcription or product. Such methods for evaluating signal transduction mediated via Ca²⁺ and cyclic nucleotide level changes are described in commonly assigned pending U.S. patent application Serial Nos. 07/563,751 and 07/962,238 and corresponding PCT application No. US91/05625.

In addition, cation-based assays (as described herein) can be employed for monitoring receptor-induced changes in intracellular cyclic nucleotide levels. Such assays employ host cells expressing cyclic nucleotide-gated ion channels. These channels, which occur in, for example, rod photoreceptor cells, olfactory cells and bovine kidney cells (see, for example, Kaupp et al., in Nature 342:762-766 (1989), with reference to EMBL accession no. X51604; Dhallan et al., in Nature 347:184-187 (1990), with reference to EMBL accession no. X55519; and Biel et al., in Proc. Natl. Acad. Sci. USA 91:3505-3509 (1994), with reference to EMBL accession no. X59668, respectively), are permeable to cations upon activation by binding of cAMP or cGMP. Thus, in assays useful in the practice of the present invention, host cells expressing endogenous or recombinant cyclic nucleotide-gated channels are transfected (or injected) with nucleic acids encoding receptors suspected of influencing cyclic nucleotide levels (e.g., metabotropic glutamate receptor-encoding DNA), and then monitored for changes in the amount of cyclic nucleotide activation of the channels. Measuring changes in cyclic nucleotide activation of channels allows one to indirectly identify as functional those receptors that

cause a change in cAMP or cGMP levels when activated. The change in the amount of activation of the cyclic nucleotide-gated channels can be determined by measuring ion flux through the channel either by electrophysiological measurement of currents or by measuring a change in intracellular cation levels (e.g., by fluorescence measurement of intracellular calcium).

In assays of cells expressing receptor species that cause a decrease in cyclic nucleotides upon activation (e.g., some metabotropic glutamate receptors), it may be preferable to expose the cells to agents that increase intracellular levels of cyclic nucleotides (e.g., forskolin and 3-isobutyl-1-methylxanthine (IBMX)) prior to adding a receptor-activating compound to the cells in the assay.

Host cells suitable for use in the above-described assay include any host cells suitable for expression of the receptor being studied (e.g., L cells, HEK293 cells, CHO cells or Xenopus oocytes for assays of metabotropic glutamate receptors). The cells can be sequentially transfected (or injected) with nucleic acids encoding a cyclic nucleotide-gated channel and receptor-encoding nucleic acids, or the cells can be co-transfected with the two nucleic acids. Transient or stable transfection, as described in Examples 3A and 3B, can be carried out.

Cells transfected (or injected) with cyclic nucleotide-gated channel nucleic acid are incubated (typically for ~24-48 hours) before testing for function. The activity of the channels can be assessed using inside-out membrane patches pulled from the transfected cells (so that the concentration of cAMP reaching the cytoplasmic face can be controlled). The transfectants can also be analyzed by single-cell video imaging or automated fluorescence analysis of internal calcium levels ($[Ca^{2+}]_i$).

This method allows analysis of cyclic nucleotide-gated channel activity by measurement of intracellular calcium levels, which change with the amount of calcium influx through the channel, as regulated by cyclic nucleotide
5 activation of the channel. The imaging assay can be conducted essentially as described in Example 3.C.4.b, and the automated fluorescence assay can be conducted as described in Example 3.c.1.

Cation-based assays can also be used to monitor
10 activation and inhibition of mGluRs that are coupled to G-proteins that also couple to voltage-gated ion channels, e.g., calcium channels. Interaction of such mGluRs with G-proteins results in opening or typically closing of the ion channel, which can be detected through
15 electrophysiological or Ca^{2+} -sensitive indicator-based assays of ion flux. When the function of this class of mGluRs is to be analyzed through measurement of cation flux, the host cell used for expression of the recombinant mGluRs must also express endogenous or heterologous
20 voltage-gated ion channels, preferably calcium channels (see, for example, commonly assigned pending U.S. patent application Serial Nos. 07/482,384, 07/914,231, 07/745,206, 08/105,536, 08/149,097, 08/311,363, 08/314,083, 08,193,078, 08/223,305 and 08/290,012 and corresponding PCT application
25 nos. US89/01408, US92/06903 and US91/01124). Thus, to examine possible mGluR6 regulation of voltage-gated calcium channels, cells transfected with DNA encoding mGluR6 can be co-transfected with DNA encoding voltage-gated calcium channel subunits (e.g., L-type, N-type or P-type channels)
30 and analyzed for calcium channel activity under various conditions. For example, the currents generated upon membrane depolarization (either through voltage pulse or exposure to K^+) before and after incubation of the cells with agonist (e.g., glutamate, L-AP4 or L-SOP) can be
35 compared. Functional coupling of the mGluR6 receptor to voltage-gated calcium channels would be revealed as a

change (e.g., decrease) in the current measured in the presence of agonist, relative to current measured in the absence of agonist. It is also possible that mGluRs that cause a change in intracellular second messenger systems, e.g., cyclic nucleotide levels, may indirectly regulate voltage-gated calcium channel activity (e.g., via protein kinases, and the like). Functional analysis of these mGluRs can also be accomplished through examination of mGluR agonist effects on calcium channel activity in cells co-expressing recombinant mGluRs and voltage-gated calcium channels, as described above.

The DNA, mRNA, vectors, receptor subtypes, and cells provided herein permit production of selected metabotropic glutamate receptor subtypes, as well as antibodies to said receptor subtypes. This provides a means to prepare synthetic or recombinant receptors and receptor subtypes that are substantially free of contamination from many other receptor proteins whose presence can interfere with analysis of a single metabotropic glutamate receptor subtype. The availability of desired receptor subtypes makes it possible to observe the effect of a drug substance on a particular receptor subtype or combination of metabotropic glutamate receptor subtypes, and to thereby perform initial *in vitro* screening of the drug substance in a test system that is specific for humans and specific for a human metabotropic glutamate receptor subtype or combination of metabotropic glutamate receptor subtypes. The availability of specific antibodies makes it possible to identify the subtype combinations expressed *in vivo*. Such specific combinations can then be employed as preferred targets in drug screening.

The ability to screen drug substances *in vitro* to determine the effect of the drug on specific receptor compositions should permit the development and screening of receptor subtype-specific or disease-specific drugs. Also,

testing of single receptor subtypes or specific combinations of various receptor subtypes with a variety of potential agonists or antagonists provides additional information with respect to the function and activity of the individual subtypes and should lead to the identification and design of compounds that are capable of very specific interaction with one or more receptor subtypes. The resulting drugs should exhibit fewer unwanted side effects than drugs identified by screening with cells that express a variety of receptor subtypes.

Further in relation to drug development and therapeutic treatment of various disease states, the availability of DNAs encoding human metabotropic glutamate receptor subtypes enables identification of any alterations in such genes (e.g., mutations) which may correlate with the occurrence of certain disease states. In addition, the creation of animal models of such disease states becomes possible, by specifically introducing such mutations into synthetic DNA sequences which can then be introduced into laboratory animals or in vitro assay systems to determine the effects thereof.

Invention DNA and mutants thereof may also be expressed in non-human transgenic animals to facilitate the analysis of mGluRs and their role in normal and pathological function of the CNS. Methods of generating transgenic animals are well known in the art (see, e.g., Hammer et al., in Nature 315:680-683 (1985)).

In another aspect, the invention comprises functional peptide fragments, and functional combinations thereof, encoded by the DNAs of the invention. Such functional peptide fragments can be produced by those skilled in the art, without undue experimentation, by eliminating some or all of the amino acids in the sequence not essential for the peptide to function as a glutamate

receptor. A determination of the amino acids that are essential for glutamate receptor function is made, for example, by systematic digestion of the DNAs encoding the peptides and/or by the introduction of deletions into the DNAs. The modified (e.g., deleted or digested) DNAs are expressed, for example, by transcribing the DNA and then introducing the resulting mRNA into *Xenopus* oocytes, where translation of the mRNAs will occur. Functional analysis of the proteins thus expressed in the oocytes is accomplished by exposing the oocytes to ligands known to bind to and functionally activate glutamate receptors, and then monitoring the oocytes to see if endogenous channels are in turn activated. If currents (or alterations in currents present in the absence of ligand) are detected, the fragments are functional as glutamate receptors.

In accordance with still another embodiment of the present invention, there is provided a method for identifying compounds which bind to human metabotropic glutamate receptor subtype mGluR6, said method comprising employing receptor proteins of the invention in a competitive binding assay. Such an assay can accommodate the rapid screening of a large number of compounds to determine which compounds, if any, are capable of displacing specifically bound [³H] glutamate or [³H]-L-AP4 or the like, i.e., binding to metabotropic glutamate receptors. Subsequently, more detailed assays can be carried out with those compounds found to bind, to further determine whether such compounds act as modulators, agonists or antagonists of invention receptors.

Another application of the binding assay of the invention is the assay of test samples (e.g., biological fluids) for the presence or absence of receptors of the present invention. Thus, for example, serum from a patient displaying symptoms related to glutamatergic pathway dysfunction can be assayed to determine if the observed

symptoms are perhaps caused by over- or under-production of such receptor subtype(s).

The binding assays contemplated by the present invention can be carried out in a variety of ways, as can readily be identified by those of skill in the art. For example, competitive binding assays can be employed, such as radioreceptor assays, and the like.

In accordance with a further embodiment of the present invention, there is provided a bioassay for identifying compounds which modulate the activity of human metabotropic glutamate receptor subtype mGluR6 of the invention, said bioassay comprising:

- (a) exposing cells containing DNA encoding human metabotropic glutamate receptor subtype(s), wherein said cells express functional metabotropic glutamate receptors, to at least one compound whose ability to modulate the activity of said receptors is sought to be determined; and thereafter
- (b) monitoring said cells for changes in second messenger activity.

The above-described bioassay enables the identification of agonists, antagonists and allosteric modulators of human metabotropic glutamate receptor subtype mGluR6. According to this method, recombinant metabotropic glutamate receptors are contacted with an "unknown" or test substance (in the further presence of a known metabotropic glutamate agonist, when antagonist activity is being tested), the second messenger activity of the known glutamate receptor is monitored subsequent to the contact with the "unknown" or test substance, and those substances which increase or decrease the second messenger response of the known glutamate receptor(s) are identified as functional ligands (i.e., modulators, agonists or

antagonists) for human metabotropic glutamate receptors. Second messenger activities which can be monitored include changes in the concentration of intracellular calcium ions, IP_3 , CAMP and cGMP levels, or monitoring of arachidonic acid release or activation or inhibition of ion current (when the host cell expresses ion channels responsive to the second messenger activities).

In accordance with a particular embodiment of the present invention, recombinant human metabotropic glutamate receptor-expressing mammalian cells or oocytes can be contacted with a test compound, and the modulating effect(s) thereof can then be evaluated by comparing the metabotropic glutamate receptor-mediated response in the presence and absence of test compound, or by comparing the metabotropic glutamate receptor-mediated response of test cells, or control cells (i.e., cells that do not express metabotropic glutamate receptors), to the presence of the compound.

As used herein, a compound or signal that "modulates the activity of a metabotropic glutamate receptor subtype" refers to a compound or signal that alters the activity of metabotropic glutamate receptors so that activity of the metabotropic glutamate receptor is different in the presence of the compound or signal than in the absence of the compound or signal. In particular, such compounds or signals include agonists and antagonists. The term agonist refers to a substance or signal, such as glutamate, L-2-amino-4-phosphonobutyrate (L-AP4), 1-amino-cyclopentyl-1,3-dicarboxylic acid (ACPD) or L-serine-O-phosphate (L-SOP), that activates receptor function; and the term antagonist refers to a substance that blocks agonist-induced receptor activation. Antagonists include competitive and non-competitive antagonists. A competitive antagonist (or competitive blocker) interacts with or near the site specific for the agonist (e.g., ligand or

neurotransmitter) for the same or closely situated site. A non-competitive antagonist or blocker inactivates the functioning of the receptor by interacting with a site other than the site that interacts with the agonist.

5 As understood by those of skill in the art, assay methods for identifying compounds that modulate human metabotropic glutamate receptor activity (e.g., agonists and antagonists) generally require comparison to a control. One type of a "control" cell or "control" culture is a cell
10 or culture that is treated substantially the same as the cell or culture exposed to the test compound, except the control culture is not exposed to test compound. For example, in methods that use voltage clamp electrophysiological procedures, the same cell can be
15 tested in the presence and absence of test compound, by merely changing the external solution bathing the cell. Another type of "control" cell or "control" culture may be a cell or a culture of cells which are identical to the transfected cells, except the cells employed for the
20 control culture do not express the recombinant human metabotropic glutamate receptor subtype(s) expressed in the transfected cells. In this situation, the response of test cell to test compound is compared to the response (or lack of response) of receptor-negative (control) cell to test
25 compound, when cells or cultures of each type of cell are exposed to substantially the same reaction conditions in the presence of compound being assayed.

 In accordance with yet another embodiment of the present invention, the second messenger activity of human
30 metabotropic glutamate receptors can be modulated by contacting such receptors with an effective amount of at least one compound identified by the above-described bioassay.

In accordance with yet another embodiment of the present invention, there are provided antibodies generated against the above-described receptor proteins. Such antibodies can be employed for studying receptor tissue localization, subtype composition, structure of functional domains, purification of receptors, as well as in diagnostic applications, therapeutic applications, and the like. Preferably, for therapeutic applications, the antibodies employed will be monoclonal antibodies.

10 The above-described antibodies can be prepared employing standard techniques, as are well known to those of skill in the art, using the invention receptor proteins or portions thereof as antigens for antibody production. Both anti-peptide and anti-fusion protein antibodies can be
15 used [see, for example, Bahouth et al. (1991) Trends Pharmacol Sci. vol. 12:338-343; Current Protocols in Molecular Biology (Ausubel et al., eds.) John Wiley and Sons, New York (1989)]. Factors to consider in selecting portions of the metabotropic glutamate receptor subtypes
20 for use as immunogen (as either a synthetic peptide or a recombinantly produced bacterial fusion protein) include antigenicity, accessibility (i.e., extracellular and cytoplasmic domains), uniqueness to the particular subtype, etc.

25 The availability of subtype-specific antibodies makes possible the application of the technique of immunohistochemistry to monitor the distribution and expression density of various subtypes (e.g., in normal vs diseased brain tissue). Such antibodies could also be
30 employed for diagnostic and therapeutic applications.

In accordance with still another embodiment of the present invention, there are provided methods for modulating the second messenger activity of receptor(s) of

the invention by contacting said receptor(s) with an effective amount of the above-described antibodies.

The antibodies of the invention can be administered to a subject employing standard methods, such as, for example, by intraperitoneal, intramuscular, intravenous, or subcutaneous injection, implant or transdermal modes of administration, and the like. One of skill in the art can readily determine dose forms, treatment regimens, etc, depending on the mode of administration employed.

The invention will now be described in greater detail by reference to the following non-limiting examples.

Example 1

Isolation of DNA Encoding Human

Metabotropic Glutamate Receptor Subtype mGluR6

cDNA Library Screening

A 0.6-kb PstI human cDNA fragment having some homology to nucleotides 1483-2110 of the rat mGluR6 cDNA [Nakajima et al. (1993). *J. Biol. Chem.* 266:11868-11873] was used in efforts to obtain a full length human mGluR6 clone. Thus, an amplified random- and oligo(dt)-primed Agt10 human retinal cDNA library (1×10^6 recombinants; Clontech, Palo Alto, CA) was screened for hybridization to the above-identified fragment. Hybridization was performed in 50% formamide, 5X Denhart's solution, 5X SSPE, 0.2% SDS at 42°C and the filters were washed in 0.2X SSPE, 0.2% SDS at 65°C.

The inserts of the hybridizing purified plaques were characterized by restriction enzyme mapping and DNA sequence analysis. Two of the hybridizing clones (METAB72 and METAB75) were nearly identical ~2.1-kb fragments and

contained a translation termination codon, but no translation initiation codon. Clone METAB75 differs from METAB72 at the 5' end in that METAB75 contains 67 nucleotides (see SEQ ID NO:3) which are not present in METAB72. These 67 nucleotides may represent alternative splicing of the mGluR6 primary transcript. To elucidate the structure of potential splice variants, oligonucleotides corresponding to the 5' and 3' ends of the 67 nucleotide sequence, as well as oligonucleotides corresponding to sequence located in the 5' and 3' regions of the mGluR6 cDNA, could be used in nucleic acid amplification of human genomic DNA. Alternatively, human genomic DNA can be screened for hybridization to the 67 nucleotide sequence, and any resulting hybridizing clone(s) analyzed.

To obtain DNA corresponding to the 5' end of the mGluR6 cDNA, a specifically-primed human retinal cDNA library was constructed and the resulting cDNAs were cloned into the λ gt10 phage vector. An oligonucleotide corresponding to the antisense of nt 1142 to 1167 in SEQ ID NO:1 was used to prime first-strand cDNA synthesis from human retinal polyA⁺ RNA. Approximately 1.6×10^6 recombinants from the λ gt10 library were screened for hybridization to a 0.6-kb SmaI fragment from METAB75 using a washing stringency of 0.2X SSPE, 0.2% SDS, 65°C. Twenty hybridizing plaques were identified in this screening, and nine putative human mGluR6 clones (METAB77 to METAB85) were isolated.

DNA sequence analysis of clones METAB84 and METAB85 revealed that they both contain the translation initiation codon. The 3' ends of these clones overlap the 5' end of METAB75.

Preparation of Full-Length mGluR6 cDNA Constructs

A full-length construct encoding the complete human mGluR6 was generated and incorporated into an expression vector for use in preparing in vitro transcripts of the cDNA and/or expression of the cDNA in mammalian cells. The base expression vector typically used is pCMV-T7-3(-SD/SA) or pCMV-T7-2(-SD/SA). Plasmid pCMV-T7-2(-SD/SA) is a pUC19-based vector that contains a cytomegalovirus (CMV) promoter/enhancer, a T7 bacteriophage RNA polymerase promoter positioned downstream of the CMV promoter/enhancer, an SV40 polyadenylation signal downstream of the T7 promoter, and a polylinker between the T7 promoter and the polyadenylation signal. This vector thus contains all the regulatory elements required for expression of heterologous DNA in a mammalian host cell, wherein the heterologous DNA has been incorporated into the vector at the polylinker. In addition, because the T7 promoter is located just upstream of the polylinker, this plasmid can be used for synthesis of in vitro transcripts of heterologous DNA that has been subcloned into the vector at the polylinker. pCMV-T7-2(-SD/SA) and pCMV-T7-3(-SD/SA) differ only in the orientation of the restriction sites in the polylinker.

To prepare a full-length mGluR6 construct (see SEQ ID NO:1), portions of clones METAB75 and METAB85 were ligated together. Initially, the inserts of METAB75 and METAB85 were separately transferred from λ gt10 as EcoRI fragments into EcoRI-digested pGEM-7Zf (Promega, Madison, WI) for ease of manipulation. The pGEM-7Zf vector containing the METAB85 insert was digested with EcoRI/ScaI to release a 1.0-kb fragment containing the 5' portion of the mGluR6 cDNA (nucleotides 39-1108 of SEQ ID NO:1). The pGEM-7Zf vector containing the insert of METAB75 was digested with ScaI/HindIII to release a 2.0-kb fragment containing the 3' portion of the mGluR6 cDNA (nucleotides

1109-2961 of SEQ ID NO:1), and this fragment was ligated with the 1.0-kb fragment from METAB85 and *EcoRI/HindIII*-digested pCMV-T7-2(-SD/SA) to create pCMV-2(-SD/SA)-hmGluR6 (see Figure 1).

5 In summary, construct pCMV-2(-SD/SA)-hmGluR6 contains 46 bp of 5' untranslated sequence from METAB85 (nucleotides 39-84 of SEQ ID NO:1) and a complete coding sequence (nucleotides 85-2718 of SEQ ID NO:1) for the mGluR6 receptor, as well as 243 bp of 3' untranslated
10 sequence (nucleotides 2719-2961 of SEQ ID NO:1). The mGluR6-encoding sequence is operatively linked to the regulatory elements in pCMV-T7-2(-SD/SA) for use in expressing the receptor in mammalian host cells and for use in generating in vitro transcripts of the DNA to be
15 expressed in *Xenopus* oocytes.

Example 2

Expression of Recombinant Human Metabotropic Glutamate Receptors in Oocytes

Xenopus oocytes are injected with in vitro
20 transcripts prepared from constructs containing DNA encoding human metabotropic receptors. Electrophysiological measurements of the oocyte transmembrane currents are made using the two-electrode voltage clamp technique (see e.g., Stuhmer (1992) *Meth.*
25 *Enzymol.* 207:319-339).

A. Preparation of In Vitro Transcripts

Recombinant capped transcripts of metabotropic receptor cDNAs contained in construct pCMV-2(-SD/SA)-hmGluR6 can be synthesized from linearized plasmids using
30 the Megascript Kit (Cat. #1334, Ambion, Inc., Austin, TX). The mass of each synthesized transcript is determined by UV

absorbance and the integrity of each transcript is determined by electrophoresis through an agarose gel.

B. Electrophysiology

Xenopus oocytes are injected with 10-50 ng of
5 metabotropic receptor transcripts per oocyte. In order to
detect functional expression of mGluRs that, upon
activation, induce a decrease in cyclic nucleotide levels
and/or directly couple to ion channels, the oocytes can
also be injected with transcripts encoding ion channels,
10 e.g., transcripts prepared from DNA encoding cyclic-
nucleotide-gated cation channels or voltage-gated calcium
channels. The preparation and injection of oocytes are
carried out as described by Dascal [(1987) Crit. Rev.
Biochem. 22:317-387]. Two-to-six days following mRNA
15 injection, the oocytes are examined using the two-electrode
voltage clamp technique. The cells are bathed in Ringer's
solution (115 mM NaCl, 2.5 mM KCl, 1.8 mM CaCl₂, 10 mM
HEPES, pH 7.3), and the membrane potential is clamped at
-80 to -100 mV. Drugs are applied by continuous bath
20 perfusion at a flow rate of 5-10 ml/min. Data are sampled
at 5-100 Hz with a Labmaster or Digidata data acquisition
board in PC-386 using AXOTAPE version 2.0 (Axon
Instruments, Foster City, CA) or PClamp 6.02 software.
Data are exported to a laser printer or plotted and
25 analyzed using Prizm version 1.2.

Metabotropic receptor-modulating compounds, i.e.,
0.1-1000 μ M L-serine-O-phosphate (L-SOP), 0.1-1000 μ M
glutamate and 0.1-1000 μ M L-2-amino-4-phosphonobutyrate
(L-AP4) are applied to the bath and the transmembrane
30 currents before and after application are recorded. Upon
activation of the recombinant mGluRs, a change in the
magnitude and/or biophysics of the current is detected
relative to the current measured in the absence of agonist.
Activation of mGluRs that cause a decrease in cyclic

nucleotide levels typically results in a decrease in the magnitude of the current. Dose-response studies in which the currents measured after application of varying amounts of agonist are compared are thus expected to reveal that the current magnitude decreases with increasing concentration of agonist. Analysis of these data enables a calculation of EC_{50} values for each compound which is used in determining the relative potencies of the compounds.

Example 3

10 Recombinant Expression of Human Metabotropic Glutamate Receptor Subunits in Mammalian Cells

Mammalian cells, e.g., human embryonic kidney (HEK 293), baby hamster kidney (BHK), Ltk⁺, GH3 and Chinese hamster ovary (CHO) cells (i.e, DG44 cells; see Urlaub et al. (1986) *Som. Cell. Molec. Genet.* 12:555), are transfected with DNA encoding human metabotropic receptors. Transfectants are analyzed for expression of metabotropic receptors using various assays, e.g., cAMP assays, cGMP assays, adenylate cyclase assays, phosphodiesterase assays, inositol phosphate (IP_1) assays, Ca^{2+} -sensitive fluorescent indicator-based assays, and [3H]-glutamate and [3H]-L-AP4 binding assays.

A. Transient Transfection of Mammalian Cells

Mammalian host cells are transiently transfected with DNA encoding mGluR6. Approximately 2×10^6 cells are transiently transfected with 5-18 μg of the mGluR6 DNA-containing plasmid according to standard $CaPO_4$ transfection procedures [see Wigler et al. (1979) *Proc. Natl. Acad. Sci. USA* 76:1373-1376]. In addition, 0.5-2 μg of plasmid pCMV β gal (Clontech Laboratories, Palo Alto, CA), which contains the *Escherichia coli* β -galactosidas gene fused to the CMV promoter, are co-transfected as a reporter gene for monitoring the efficiency of transfection. As a positive

control for the efficiency of transfection, the transfectants are analyzed for β -galactosidase expression by direct staining of the product of a reaction involving β -galactosidase and the X-gal substrate [Jones (1986) *EMBO* 5:3133-3142]. Transfectants can also be analyzed for β -galactosidase expression by measurement of β -galactosidase activity [Miller (1972) in *Experiments in Molecular Genetics*, pp.352-355, Cold Spring Harbor Press].

If the cells that are transiently transfected with hmGluR6 DNA linked to the MMTV promoter for inducible expression of mGluR6 do not express, or express only low levels of endogenous glucocorticoid receptors, they can be co-transfected with 5 μ g of pRShGR (ATCC accession no. 67200), which contains DNA encoding a glucocorticoid receptor operatively linked to the Rous Sarcoma virus (RSV) LTR promoter. Co-expression of glucocorticoid receptors in these cells should insure that induction of expression of the MMTV promoter-mGluR6 cDNA occurs upon addition of glucocorticoids (e.g., dexamethasone) to the cells.

The mammalian host cells can also be transiently co-transfected with DNA encoding cyclic nucleotide-gated ion channels or voltage-gated calcium channels. Such cells are particularly useful in evaluating functional expression of mGluRs that cause a decrease in cyclic-nucleotide levels and/or directly couple to ion channels upon activation. Cells expressing both ion channels and mGluRs of this type can be analyzed by ion-flux detection methods, i.e., electrophysiologically or Ca^{2+} -sensitive indicator-based assays, to evaluate mGluR function.

The efficiency of transfection of mammalian cells is expected to be typical of standard efficiencies (i.e., ~50%).

B. Stable Transfection of Mammalian Cells

Mammalian cells, such as HEK 293, Ltk⁻, BHK and CHO cells (e.g., DG44 cells), can be stably transfected using the calcium phosphate transfection procedure [Current
5 *Protocols in Molecular Biology*, Vol. 1, Wiley Inter-Science, Supplement 14, Unit 9.1.1-9.1.9 (1990)]. When CHO cells are used as hosts, it is generally preferable to use the SV40 promoter to regulate expression of the human metabotropic receptor-encoding cDNA. Ten-cm plates, each
10 containing $1-2 \times 10^6$ cells, are transfected with 1 ml of DNA/calcium phosphate precipitate containing approximately 5-10 μ g of metabotropic receptor-encoding DNA and 0.5-1 μ g of DNA encoding a selectable marker, for example, the neomycin-resistance gene (i.e., pSV2neo) for selection of
15 HEK 293 transformants, the thymidine kinase gene for Ltk⁻ cell transfectants, the dihydrofolate reductase (dhfr) gene for selection of DG44 cell transformants, and the like. After -14 days of growth in the appropriate selective media, colonies form and are individually isolated using
20 cloning cylinders. The isolates are then subjected to limiting dilution and screened to identify those that express metabotropic receptors using, for example, methods described below.

C. Analysis of Transfectants

25 1. Fluorescent indicator-based assays

Activation of G-protein-coupled metabotropic receptors by agonists leads to stimulation of the phosphatidylinositol (PI) hydrolysis/intracellular Ca^{2+}
30 signalling pathway and/or the inhibitory cAMP or cGMP cascade. Additionally, it is possible that some mGluRs can couple to G-proteins that are directly coupled to voltage-gated calcium channels. Because each of these possible effects of mGluR activation can regulate Ca^{2+} levels within

the cell, methods of detecting transient changes in intracellular calcium concentration can be applied to the analysis of functional expression of such metabotropic receptors. One method for measuring intracellular calcium levels relies on calcium-sensitive fluorescent indicators.

Calcium-sensitive indicators, such as fluo-3 and fura-2 (Molecular Probes, Inc., Eugene, OR) are available as acetoxymethyl esters which are membrane permeable. When the acetoxymethyl ester form of the indicator enters a cell, the ester group is removed by cytosolic esterases, thereby trapping the free indicator in the cytosol. Interaction of the free indicator with calcium results in increased fluorescence of the indicator; therefore, an increase in the intracellular Ca^{++} concentration of cells containing the indicator can be expressed directly as an increase in fluorescence (or an increase in the ratio of the fluorescence at two wavelengths when fura-2 is used). An automated fluorescence detection system for assaying metabotropic receptors has been described in commonly assigned pending US Patent Application No. 08/229,150 and corresponding PCT Patent Application No. US92/11090, both of which are hereby incorporated by reference herein. Additionally, fluorescence imaging techniques can be utilized to visualize intracellular Ca^{++} oscillations.

Mammalian cells that are stably or transiently transfected with DNA encoding a human mGlu receptor can be analyzed for expression of functional recombinant metabotropic receptors using the automated fluorescent indicator-based assay and the fluorescence imaging assay. If the mGluR is a type that effects a cellular response through inhibition of adenylate cyclase or cGMP-specific phosphodiesterase, and thereby leads to a decrease in cyclic nucleotide levels, the host cell should also express endogenous or heterologous cyclic nucleotide-gated calcium

channels to enable analysis of the mGluR using the fluorescent indicator-based assay (see, for example, Example 3.C.4.b). Likewise, if the mGluR is a type that couples to G-proteins which are directly coupled to voltage-gated calcium channels, the host cell must express endogenous or heterologous voltage-gated calcium channels.

a. Automated fluorescence assay

Untransfected mammalian host cells (or host cells transiently transfected with the base expression vector lacking mGluR-encoding DNA and mammalian host cells that have been transfected with mGluR-encoding DNA are plated in the wells of a 96-well microtiter dish (Nunc Catalog No. 1-6708, distributed by Alameda Industries, Escondido, CA) that have been precoated with poly-L-lysine at a density of 2×10^5 cells/well and loaded with fluo-3 by incubation for 2 hours at 20°C in a medium containing 20 μ M fluo-3, 0.2% Pluronic F-127 in HBS (125 mM NaCl, 5 mM KCl, 1.8 mM CaCl_2 , 0.62 mM MgCl_2 , 20 mM glucose, 20 mM HEPES, pH 7.4). The cells are then washed with assay buffer (i.e. HBS). The microtiter dish is then placed into a fluorescence plate reader (e.g., Fluoroskan II, Lab Products International, Ltd., Raleigh, NC), and the basal fluorescence of each well measured and recorded before addition of metabotropic receptor-modulating compounds such as quisqualate, glutamate, L-AP4, trans-ACPD (i.e., 1-amino-cyclopentane-1,3-dicarboxylic acid), 1S,3R-ACPD, AP3 (i.e., 2-amino-3-phosphonopropionate), AP5 (i.e., 2-amino-5-phosphopentanoate), and CNQX (i.e., 6-cyano-7-nitroquinoxaline-2,3-dione) to the wells. The fluorescence of the wells is monitored repeatedly (75 readings at 0.63-sec intervals) following addition of agonist.

In general, the fluorescence of the untransfected host cells is not expected to change after addition of any of these compounds. The fluorescence of host cells

transfected with the mGluR construct is expected to increase (if the mGluR being expressed is coupled to the PI hydrolysis pathway) or decrease (if the mGluR being expressed is coupled to inhibition of cyclic nucleotide generation or directly coupled to voltage-gated calcium channels) in response to application of agonist. In assays of mGluR that cause a decrease in cyclic nucleotide levels upon activation, it may be desirable to expose the cells (which also express cyclic nucleotide-gated channels) to forskolin and IBMX to elevate cyclic nucleotide levels and thereby enhance the detection of the signal resulting from the mGluR-induced decrease in cyclic nucleotide levels.

Dose-response studies in which the peak fluorescence values measured after application of varying amounts of mGluR agonists to cells transfected with mGluR-encoding DNA are compared, are expected to reveal that the magnitude of the peak fluorescence after addition of agonist changes with increasing concentration of each compound. Analysis of these data enables a calculation of EC₅₀ values for each compound used in determining the relative potencies of the compounds.

Mammalian host cells co-transfected with mGluR-encoding DNA linked to the MMTV inducible promoter and pRShGR (a glucocorticoid receptor construct) can also be analyzed in the fluorescence assay. The fluorescence of these cells changes in response to mGluR agonists; the peak response is greater when the cells are preincubated with dexamethasone (~1 μ M) for 16 hrs at 37°C before being assayed.

30

b. Fluorescence imaging assay

Mammalian host cells that have been transfected with mGluR-encoding DNA and untransfected host cells (control) are analyzed by digital video imaging in order to

visualize metabotropic receptor-mediated changes in intracellular Ca^{++} concentration. Transfectants (4×10^5 cells per 35-mm culture dish with glass-insert bottom) are loaded with fura-2 by exposing the cells to $1 \mu\text{M}$ fura-2 (acetoxymethyl ester) for 25 min at room temperature in the dark. The cells are then washed three times with DMEM and four times with Ringer's (160 mM NaCl, 5 mM KCl, 2 mM CaCl_2 , 1 mM MgCl_2 , 11 mM glucose, 5 mM HEPES, pH 7.3) solution.

The transfectants and untransfected cells are then placed on the stage of an Axiovert 100 TV inverted microscope (Zeiss, Oberkochen, Germany) equipped with a 150 W xenon lamp as the UV light source. An Image 1 Fluor System (Universal Imaging, West Chester, PA) is used to control the alternate excitation of the cells at 350 and 380 nm (typically every 3 sec) through a 40X 1.3 N.A. oil immersion objective. Light emitted at greater than 510 nm is collected by a CCD 72 intensified CCD camera (MTI Dage, Michigan City, IN) and digitized. The background emitted light is subtracted from the 350 and 380 nm excitation images. The corrected values are used in calculating the 350/380 intensity ratio. These uncalibrated fura-2 ratio values are reliable indicators of changes in the intracellular Ca^{++} concentration.

The uncalibrated fura-2 ratios are used to generate pseudocolor images with purple corresponding to resting intracellular Ca^{++} concentration (~ 100 nM) and red to high intracellular Ca^{++} concentration ($\sim 1 \mu\text{M}$). For quantitative analysis, the average ratio value in a 12-by-12 pixel region over each cell is calculated by the software for each ratio image in an experiment and imported into a spreadsheet for further analysis and graphing.

To demonstrate that HEK 293 cells express the intracellular components required in receptor-mediated activation of the PI hydrolysis/ Ca^{++} mobilization pathway,

transfectants and untransfected cells (which express endogenous G-protein-coupled muscarinic acetylcholine receptors) are exposed to 1 mM carbamylcholine (CCh; a muscarinic acetylcholine receptor agonist), and the cells
5 are monitored for increases in intracellular Ca^{++} concentration. Typically, a detectable increase in the intracellular Ca^{++} concentration of the majority of the cells is observed in response to CCh addition in the imaging studies.

10 Both mGluR- transfected and untransfected HEK 293 cells are also monitored for changes in intracellular Ca^{++} concentration in response to mGluR agonists. On average, the intracellular Ca^{++} concentration of the untransfected cells is not expected to change after exposure to agonist.
15 In contrast, the intracellular Ca^{++} concentration of a significant percentage of the transfected cells is expected to change in response to application of agonist.

2. Phosphatidylinositol hydrolysis (IP_1) assays

Because activation of G-protein-coupled
20 metabotropic receptors by agonists can lead to stimulation of the phosphatidylinositol (PI) hydrolysis pathway, methods of detecting increases in the products of PI hydrolysis (e.g., IP_3 , IP_2 or IP_1) can be applied to the analysis of functional expression of metabotropic receptors
25 that are coupled to the PI hydrolysis/ Ca^{++} mobilization pathway or to both the PI hydrolysis/ Ca^{++} mobilization pathway and the inhibitory cAMP cascade. One method for measuring IP_1 and/or IP_2 and/or IP_3 generated by hydrolysis of PI involves incorporation of [^3H]-myo-inositol into cell
30 membrane phospholipids and subsequent separation of [^3H]- IP_1 , [^3H]- IP_2 and [^3H]- IP_3 , followed by quantitation of the radioactivity in each fraction, as follows.

Mammalian cells that have been transiently transfected with DNA encoding an mGluR that couples to the PI hydrolysis pathway are plated in 24-well microtiter plates at a density of 8×10^5 cells/well. After the cells are allowed to settle and adhere to the bottom of the plate for a few hours, 2 μ Ci of [3 H]-myo-inositol (Amersham catalog # PT6-271, Arlington Heights, IL; specific activity = 17.7 Ci/mmol) is added to each well and incubated overnight at 37°C. The next day, the cells are examined under a Nikon Diaphot inverted microscope to assess the health of the cells morphologically as well as to determine if the wells contained a confluent layer of cells. Media is then aspirated and the cells are washed twice with 0.5 ml Krebs bicarbonate buffer [117.9 mM NaCl, 4.72 mM KCl, 2.54 mM CaCl_2 , 1.18 mM MgSO_4 , 1.19 mM KH_2PO_4 , 25 mM NaHCO_3 , 11.1 mM dextrose (equilibrated with 95% O_2 , 5% CO_2 , pH 7.4)]. The cells are incubated for 45 min. at room temperature. The buffer is then aspirated from each well and the cells are washed and incubated in 0.5 ml/well for 45 min at room temperature. The buffer is aspirated from each well, and the cells are then incubated for 20 min at 37°C with 450 μ l Krebs-bicarbonate buffer containing 10 mM LiCl instead of 10 mM NaCl (to block hydrolysis of IP₁ to inositol and inorganic phosphate) and 10 mM unlabeled myo-inositol.

To begin treatment of the cells with metabotropic receptor-modulating compounds, 50 μ l of Krebs-bicarbonate buffer (control) or 10x the final concentration of the compound is added to each well and the incubation is continued for 40 min. Incubation is terminated by addition of 1 ml ice-cold methanol to each well.

In order to isolate IP₁ from the cells, the cells are removed from the plates by scraping with plastic pipette tips, and the cell suspension is transferred to 12 x 75 mm glass tubes. The tubes are thoroughly vortexed,

and a 150- μ l aliquot, i.e., one-tenth of the total volume, of each reaction mixture is transferred to another tube for protein determination. The water-soluble inositol phosphates are separated from the radiolabelled membrane phospholipids by extraction in 1 ml chloroform. The tubes are incubated at room temperature for 30 min before centrifugation at 500 x g for 5 min at 4°C. The aqueous (top) layer containing the [3 H]-inositol phosphates is transferred to 10-ml syringes connected to Accell QMA SEP-PAK columns (Millipore; California), which are attached to an Amersham Superseparator apparatus that is modified to allow collection into 20-ml scintillation vials. Water (10 ml) is added to the cartridge to remove [3 H]-inositol precursor, followed by 4 ml 0.02 M triethylammonium hydrogen carbonated buffer (TEAB, Fluka; New York). To separately remove [3 H]-IP₁, [3 H]-IP₂ and [3 H]-IP₃ from the cartridge, 4 ml of 0.1 M TEAB, 4 ml of 0.3 M TEAB and 4 ml of 0.4 M TEAB are sequentially added to the cartridge and the separate eluate fractions are collected in large scintillation vials. Ecolume cocktail (15 ml; ICN; California) is added to each vial for subsequent scintillation counting to determine the amount of each IP in the separate fractions. Protein concentration is determined using the Bio-Rad Protein Micro-Assay (Bio-Rad, Richmond, CA).

To keep the basal levels of IP₁ low in cells expressing mGluRs, it may be beneficial to decrease the amount of mGluR-encoding DNA used for transfecting the cells, e.g., 0.18 μ g instead of 18 μ g. Lower basal levels enhance the detectability of IP₁ concentration increases in mGluR-expressing cells treated with an mGluR agonist.

Dose-response studies which compare the IP₁ levels measured after application of varying amounts of mGluR agonist to cells transfected with mGluR-encoding DNA reveal that IP₁ levels increase with increasing concentration of

agonist if the mGluR being expressed is coupled to the PI hydrolysis pathway. Analysis of these data enables calculation of EC_{50} values for each compound which is used in determining the relative potencies of the compounds.

5 3. Metabotropic Receptor Ligand Binding Assays

Mammalian cells transfected with mGluR-encoding DNA or with pUC19 (negative control) are analyzed for [3 H]-glutamate binding. Rat brain membranes are included in the binding assays as a positive control.

10 a. Preparation of Membranes

 i. Rat forebrain membranes

Rat forebrain membranes are prepared from rat brains as described by Schoepp et al. [(1992) *Neurosci. Lett.* 145:100]. Briefly, forebrains, consisting
15 essentially of cerebral cortex, striatum and hippocampus, from ten rat brains are homogenized in 50 volumes of 30 mM ice-cold Tris-HCl containing 2.5 mM $CaCl_2$, pH 7.6 using a Polytron (Brinkman, Westbury, NY). The homogenate is centrifuged at 30,000 x g for 15 minutes at 4°C. The
20 supernatant is discarded, the pellet resuspended in 50 volumes of buffer using a Polytron and the suspension is centrifuged at 30,000 x g for 15 min. This step is repeated twice. The pellet is resuspended in buffer and incubated at 37°C for 30 min. The suspension is then
25 centrifuged at 30,000 x g for 15 min. at 4°C. This step is repeated three times. The final pellet is resuspended in 15 volumes of 50 mM Tris-HCl, pH 7.6, buffer, aliquoted, quick frozen and stored at -70°C.

ii. Membranes from Transfected and Untransfected Mammalian Cells

In order to prepare membranes from mammalian cells transfected with mGluR-encoding DNA or pUC19 (negative control), cells are scraped from the tissue culture plates, and the plates rinsed with 5 ml of PBS (phosphate-buffered saline: 137 mM NaCl, 2.7 mM KCl, 10 mM Na₂HPO₄, 1.7 mM KH₂PO₄). The cells are centrifuged at low speed in a table-top centrifuge, and the cell pellet is rinsed with PBS. The cell pellet is resuspended in 20 volumes of 50 mM Tris-HCl containing 0.5 mM PMSF, pH 7.6. The cells are homogenized on ice in a Dounce (teflon/glass) homogenizer using 10-20 strokes. The homogenate is centrifuged at 120,000 x g for 30 min. at 4°C. The final membrane pellet is resuspended in 50 mM Tris-HCl containing 0.5 mM PMSF, pH 7.6. The membrane preparations are aliquoted, quick-frozen, and stored at -70°C. The protein concentration is determined using the method of Bradford [(1976) Anal. Biochem. 72:248].

20 b. [³H]-Glutamate binding assays

Specific binding of [³H]-glutamate to metabotropic receptors in rat forebrain membranes is determined basically as described by Schoepp et al. (*supra*). On the day of the assay, frozen homogenate is thawed and washed three times with 50 mM Tris-HCl, pH 7.6. The final pellet is resuspended in 50 mM Tris-HCl, pH 7.6. The protein concentration is determined using the method of Bradford [(1976) Anal. Biochem. 72:248]. The suspension is centrifuged at 30,000 x g for 15 min. in order to be able to resuspend the pellet in the assay buffer (50 mM Tris-HCl, 0.5 mM PMSF, 0.1% BSA, pH 7.6) at a concentration of 1 mg/ml. The membrane suspension is incubated in triplicate with 10 or 100 nM [³H]-glutamate (N w England Nuclear, Boston, MA; catalog no. NET-490, specific activity

= 57.4 Ci/mmol) in a total volume of 0.5 ml assay buffer containing 100 μ M NMDA (Sigma, St. Louis, MO), 100 μ M AMPA and 100 μ M kainate (Research Biochemicals Inc., Natick, MA) to block [3 H]-glutamate binding to ionotropic glutamate receptors and 100 μ M SITS (Sigma, St. Louis, MO) to inhibit [3 H]-glutamate binding to chloride-dependent uptake sites for 45 min on ice. Bound radioactivity is separated from free radioactivity by centrifugation for 5 min. at 20,000 x g (4°C) in an SM-24 rotor (Sorvall, Wilmington, Delaware). The pellets are washed twice with 5-6 ml of ice-cold 50 mM Tris-HCl buffer, pH 7.6. The pellets are solubilized by vortexing in 5 ml of Ecolume scintillation cocktail. The radioactivity is measured in a Beckman scintillation counter. The nonspecific binding observed in the presence of 1 mM glutamate is subtracted from the total binding in order to determine specific binding.

Specific binding of [3 H]-glutamate to membranes prepared from mammalian cells transfected with mGluR-encoding DNA or pUC19 is determined essentially as described for measuring binding to rat brain membranes with minor modifications. On the day of the assay, frozen homogenate is thawed and centrifuged in a MR-150 high-speed refrigerated microcentrifuge (Peninsula Laboratories, Inc., Belmont, CA). The pellet is washed twice with assay buffer (50 mM Tris-HCl, 0.5 mM PMSF, 0.1% BSA, pH 7.6), and the final pellet resuspended in assay buffer at a concentration of 1 mg/ml. NMDA, AMPA and kainate are excluded from the assay mixture when mammalian cell membranes are being analyzed for [3 H]-glutamate binding.

Specific binding of [3 H]-glutamate to rat brain membranes is measured using 200 μ g of membrane and 100 nM [3 H]-glutamate. The ratio of total-to-nonspecific binding is typically approximately 2:1.

Specific binding of [³H]-glutamate to membranes prepared from mammalian cells transfected with mGluR or pUC19 is measured using 200 µg of membranes and 100 nM [³H]-glutamate. The amount of specific binding to membranes prepared from mammalian cells transfected with mGluR-encoding DNA is expected to be significantly higher than that to membranes prepared from mammalian cells transfected with pUC19. Competitive binding studies can be conducted in which the amount of specific binding of [³H]-glutamate to membranes prepared from mammalian cells transfected with mGluR-encoding DNA in the presence of various concentrations of unlabeled glutamate is determined. IC₅₀ values are calculated from the data obtained in these studies.

The binding assays can also be performed using [³H]-L-AP4 (Tocris Neuramin, Bristol, U.K.) in place of [³H]-glutamate, and unlabelled L-AP4 to measure non-specific binding. The results of L-AP4 binding assays will reveal whether the mGluR being expressed in the host cell is a subtype that has affinity for L-AP4.

4. Cyclic AMP (cAMP) Assays

a. RIA-based assays

Because activation of some G-protein-coupled receptors results in decreases (as opposed to increases) in cAMP, assays that measure intracellular cAMP levels can also be used to evaluate recombinant human metabotropic receptors expressed in mammalian host cells. Mammalian cells transiently or stably transfected with human metabotropic receptor-encoding DNA or pUC19 (negative control) are plated in 24-well microtiter plates at a density of 5×10^5 cells/well and allowed to incubate overnight. The following day, cells are examined under a Nikon Diaphot inverted microscope to assess the health of

the cells morphologically as well as to determine if the wells contain a confluent layer of cells. Media is then aspirated and the cells are washed twice with 0.5 ml Krebs bicarbonate buffer (same buffer used in the PI hydrolysis assay; see Example 3.C.2) containing 1 mM IBMX (3-isobutyl-1-methylxanthine; Sigma, St. Louis, MO) and 0.1% BSA. Alternatively, 1X PBS can be used in place of Krebs bicarbonate buffer. Each wash is followed with a 30-min incubation at 37°C. The buffer is aspirated from each well and the cells are then incubated for 20 min at 37°C with 0.2 ml Krebs-bicarbonate buffer containing 1 mM IBMX and 0.1% BSA.

To begin treatment of the cells with metabotropic receptor-modulating compounds, 50 μ l of Krebs-bicarbonate buffer, with or without 5X the final concentration of forskolin, is added to some of the cells (basal control) and 5X the final concentration of the compound plus 5X the final concentration of forskolin is added to some cells (test cells) and the incubation is continued for 15 min at 37°C. At the end of this 15-min period, the reaction is terminated by adding 25 μ l of 1% Triton X-100 solution and the incubation is continued for another 10 min. The lysed cells plus the cell suspension are transferred to 12 x 75 mm polypropylene tubes with plastic pipette tips. Each well is rinsed with 75 μ l of Krebs-bicarbonate buffer containing 1 mM IBMX and 0.1% BSA. The rinse is combined with the cell lysate. The cell lysate suspension is centrifuged at 2300 x g for 5 min and the supernatant is assayed for cAMP levels using an RIA kit (Amersham Life Sciences catalog #TRK 432; Arlington Heights, IL).

b. Cyclic nucleotide-gated channel-based assay

i. Evaluation of Host Cells Expressing Cyclic Nucleotide-Gated Channels

5

Mammalian host cells, e.g., HEK293 cells, are grown in monolayers (approximately 2×10^6 cells per 10 cm poly-D-lysine-coated plate) in Dulbecco's modified Eagle's medium (DMEM; Gibco) containing 5% defined supplemented calf serum (Hyclone) including 100 U/ml penicillin and 100 μ g/ml streptomycin sulfate. The cells are transiently transfected by the calcium phosphate method (see Ausubel, et al., *supra*, pp 9.1.1-9.1.7) with 5 μ g of pCMV-OCNA (containing DNA encoding the olfactory cyclic nucleotide-gated channel (see Dhallan et al., *supra*) linked to the CMV promoter, 2 μ g pCMV- β gal (Clontech, Palo Alto, CA), and 13 μ g pUC19 as a control plasmid. The cells may optionally be co-transfected with DNA encoding a second subunit of the olfactory cyclic nucleotide-gated channel (i.e., rOCNC2; see Liman et al., *Neuron* 13:611-621 (1994) and Bradley et al., *Proc. Natl. Acad. Sci. USA* 91:8890-8894 (1994)).

Vector pCMV-OCNA is constructed by isolating the olfactory cyclic nucleotide-gated channel-encoding DNA as -3.0 kb EcoRI fragment from pBluescript KS and ligating the resulting fragment to EcoRI-digested pCMV-T7-3. Plasmid pCMV-T7-3 is essentially identical to pCMV-T7-3(-SD/SA) (see Example 1) except that it contains SV40 splice donor/splice acceptor sites positioned between the CMV promoter and the T7 promoter/enhancer.

30 Six hours after transfection, the calcium phosphate precipitate is washed off and cells fed with DMEM containing 10% dialyzed fetal bovine serum (Hyclone), 100 U/ml penicillin, 100 μ g/ml streptomycin, and supplemented

with 2 mM glutamine. Transfection efficiencies, as determined by measuring β -galactosidase activity, are typically 50-70%.

HEK cells transfected with olfactory cyclic nucleotide-gated channel DNA are incubated 24-48 hours before testing for function. The activity of the channels is first assessed electrophysiologically using inside-out membrane patches pulled from the transfected cells so that the concentration of cAMP reaching the cytoplasmic face could be controlled (see, e.g., Single-Channel Recording, Sakmann and Neher, eds., Plenum Press, N.Y. (1983)). The patch is exposed to $\text{Ca}^{++}/\text{Mg}^{++}$ -free Ringer's solution on both surfaces. In one patch, a current is elicited by ramping the membrane potential from -100 to +100 mV in 2 seconds, in the presence of 1 mM cAMP. This result suggests that the channel was functionally expressed.

The transfectants are also analyzed by single-cell video imaging of internal calcium levels ($[\text{Ca}^{++}]_i$). This method allows analysis of cyclic nucleotide-gated channel activity by measurement of intracellular calcium levels, which change with the amount of calcium influx through the channel, as regulated by cyclic nucleotide activation of the channel. The imaging assay is conducted essentially as described in Example 3.C.1.b. Software controls the alternate excitation of the cells at 350 and 385 nm (typically every 5 seconds) through a 40 X 1.3 N.A. oil immersion objective. Light emitted at greater than 510 nm is collected by the CCD camera, digitized, and 350 and 385 nm excitation images are background-subtracted before calculating the 350/385 nm intensity ratio.

For quantitative analysis, the average 350/385 ratio value in a 12 by 12 pixel region over each cell is calculated by the software for each ratio image in an experiment and imported into a spreadsheet for further

analysis and graphing. Fura-2 signals are calibrated with an intact cell in which R_{\min} is obtained by exposing the cells to Ringer's solution containing 10 μM ionomycin, 10 mM EGTA and no added Ca^{2+} . R_{\max} is next obtained by exposing
5 the cells to Ringer's solution containing 10 μM ionomycin and 10 mM Ca^{2+} , with three washes. Using a K_d of 250 nM for fura-2 inside living cells and the equation of Grynkiewicz et al. (*J. Biol. Chem.* 260:3440 (1985)), the resting $[\text{Ca}^{2+}]_i$ is typically 100 nM.

10 In these experiments, the HEK293 cell transfectants are exposed to agents which increase intracellular cAMP levels and monitored for subsequent changes in $[\text{Ca}^{2+}]_i$. There is typically a small increase in $[\text{Ca}^{2+}]_i$ in the averaged results from 64 cells, and in
15 individual cells in response to addition of 100 μM forskolin (activator of adenylyl cyclase). A more significant increase is typically observed after addition of 1 mM IBMX (inhibitor of cAMP phosphodiesterase). Few, if any, untransfected HEK 293 cells show an increase in
20 $[\text{Ca}^{2+}]_i$ in response to elevation of intracellular cAMP levels. Any such response is transient and clearly different from the sustained response seen in HEK293 cells transfected with the cyclic nucleotide-gated channel DNA.

25 These results demonstrate that HEK cells expressing cyclic nucleotide-gated channels may be used as host cells in assays of receptors that cause a change in intracellular cyclic nucleotide levels when activated (e.g., metabotropic receptors).

ii. Co-Expression of Metabotropic Glutamate Receptors and Cyclic Nucleotide-Gated Channels

Mammalian cells transfected with DNA encoding cyclic nucleotide-gated channels (e.g., pCMV-OCNA) can be simultaneously or successively co-transfected with DNA encoding human mGluRs as described in Example 3A and 3B. If the mGluR expressed in the cells is one that causes a decrease in cyclic nucleotide levels upon activation, then functional expression of the recombinant mGluR can be evaluated by analyzing the cells for decreases in intracellular Ca^{2+} levels (due to decreased cyclic nucleotide-induced activation and resulting influx of Ca^{+2} through cyclic nucleotide-gated channels) upon activation of the mGluRs.

Transfectants can be analyzed using single-cell video imaging as described in Example 3.C.4.b.(i). Application of 100 μ M forskolin and 1 mM IBMX results in an increase in the fluorescence of the cells resulting from increases in intracellular calcium levels upon opening of the cyclic nucleotide-gated channel. The forskolin/IBMX-induced fluorescence increase is detectably reduced in transfectants treated with mGluR agonist (preferably by a 2-min preincubation with agonist prior to applying forskolin/IBMX).

5. Northern Blot Hybridization Analysis

Cells transfected with human metabotropic receptor-encoding DNA can also be analyzed for expression of the corresponding transcript by northern blot analysis. Total RNA is isolated from $\sim 1 \times 10^7$ cells that have been transfected with the human metabotropic receptor-encoding DNA, and 10-15 μ g of RNA is used for northern hybridization analysis. The inserts from human metabotropic receptor-

encoding plasmids are nick-translated and used as probes. Typical conditions for northern blot hybridization and washing are as follows:

5 hybridization in 5x SSPE, 5X Denhart's solution, 50% formamide, at 42°C followed by washing in 0.2x SSPE, 0.1% SDS, at 65°C.

10 While the invention has been described in detail with reference to certain preferred embodiments thereof, it will be understood that modifications and variations are within the spirit and scope of that which is described and claimed.

That which is claimed is:

1. Isolated nucleic acid encoding human metabotropic glutamate receptor subtype mGluR6.

2. Nucleic acid according to Claim 1 wherein said nucleic acid encodes an amino acid sequence having greater than 95 % amino acid sequence identity with the sequence set forth in SEQ ID NO:2.

3. Nucleic acid according to Claim 2 wherein said nucleic acid encodes the amino acid sequence set forth in SEQ ID NO:2.

4. Nucleic acid according to Claim 2 wherein said nucleic acid hybridizes under high stringency conditions to the coding region of SEQ ID NO:1.

5. Nucleic acid according to Claim 2 wherein said nucleic acid has greater than 90 % sequence identity with the nucleotide sequence set forth in SEQ ID NO:1.

6. Nucleic acid according to Claim 2 wherein the nucleotide sequence of said nucleic acid is the same as the coding region (nucleotides 85-2718) of SEQ ID NO:1.

7. Nucleic acid according to claim 1, wherein said nucleic acid contains the 67 nucleotide sequence set forth in SEQ ID NO:3.

8. Isolated protein encoded by the nucleic acid of Claim 1.

9. Isolated protein encoded by the nucleic acid of Claim 7.

10. Nucleic acid probes comprising at least 46 contiguous bases of the DNA according to Claim 1 or the full complement thereof.

11. Nucleic acid probes comprising at least 46 contiguous bases of the DNA according to Claim 7 or the full complement thereof.

12. Eukaryotic cells containing nucleic acids according to Claim 1.

13. Eukaryotic cells expressing nucleic acids of Claim 1.

14. Amphibian oocytes expressing the nucleic acids of Claim 1.

15. A method for identifying DNA encoding human metabotropic glutamate receptor protein subtype mGluR6, said method comprising:

- 5 contacting human DNA with a probe according to Claim 10, wherein said contacting is carried out under low-to moderate-stringency hybridization conditions when the probe used is a polynucleic acid fragment, or under high-stringency hybridization conditions when the probe used is an oligonucleotide, and
- 10 identifying DNA(s) which hybridize to said probe.

16. A method for identifying DNA encoding human metabotropic glutamate receptor protein subtype mGluR6, said method comprising:

- 5 contacting human DNA with a probe according to Claim 11, wherein said contacting is carried out under low-to moderate-stringency hybridization conditions when the probe used is a polynucleic acid fragment, or under high-stringency hybridization conditions when the probe used is an oligonucleotide, and

10 identifying DNA(s) which hybridize to said probe.

17. A method for identifying compounds which bind to human metabotropic glutamate receptor subtype mGluR6, said method comprising employing a receptor protein according to Claim 8 in a competitive binding assay.

18. A method for identifying compounds which bind to human metabotropic glutamate receptor subtype mGluR6, said method comprising employing a receptor protein according to Claim 9 in a competitive binding assay.

19. A bioassay for identifying compounds which modulate the activity of human metabotropic glutamate receptor subtype mGluR6, said bioassay comprising:

- 5 (a) exposing cells of Claim 13 to at least one compound whose ability to modulate the second messenger activity of said receptor subtype(s) is sought to be determined; and thereafter
- 10 (b) monitoring said cells for changes in second messenger activity.

20. A method for modulating the second messenger activity of human metabotropic glutamate receptor subtype mGluR6, said method comprising:

- 5 contacting said receptor with an effective amount of at least one compound identified by the bioassay of Claim 19.

21. An antibody generated against the protein of Claim 8 or an immunogenic portion thereof.

22. An antibody according to Claim 21, wherein said antibody is a monoclonal antibody.

23. An antibody generated against the protein of Claim 9 or an immunogenic portion thereof.

24. An antibody according to Claim 23, wherein said antibody is a monoclonal antibody.

25. A method for modulating the second messenger activity of human metabotropic glutamate receptor subtype(s), said method comprising:

contacting said receptor with an effective amount
5 of the antibody of Claim 21.

26. A method for modulating the second messenger activity of human metabotropic glutamate receptor subtype(s), said method comprising:

contacting said receptor with an effective amount
5 of the antibody of Claim 23.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/LS 96/03662

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
Please see Further Information sheet enclosed.
2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.

INTERNATIONAL SEARCH REPORT

International Application No. PCT/US96/03662

FURTHER INFORMATION CONTINUED FROM PCT/ISA/210

Remark : As far as claims 20, 25, 26 are directed to a method of treatment of (diagnostic method practised on) the human/animal body the search has been carried out and based on the alleged effects of the compound/composition.
